

## Objective

Today, we're taking what we learned yesterday about [Inheritance](#) and extending it to [Abstract Classes](#). Because this is a very specific Object-Oriented concept, submissions are limited to the few languages that use this construct. Check out the [Tutorial](#) tab for learning materials and an instructional video!

## Task

Given a *Book* class and a *Solution* class, write a *MyBook* class that does the following:

- Inherits from *Book*
- Has a parameterized constructor taking these **3** parameters:
  1. string *title*
  2. string *author*
  3. int *price*
- Implements the *Book* class' abstract *display()* method so it prints these **3** lines:
  1. **Title:**, a space, and then the current instance's *title*.
  2. **Author:**, a space, and then the current instance's *author*.
  3. **Price:**, a space, and then the current instance's *price*.

**Note:** Because these classes are being written in the same file, you must not use an access modifier (e.g.: **public**) when declaring *MyBook* or your code will not execute.

## Input Format

You are not responsible for reading any input from stdin. The *Solution* class creates a *Book* object and calls the *MyBook* class constructor (passing it the necessary arguments). It then calls the *display* method on the *Book* object.

## Output Format

The *void display()* method should print and label the respective *title*, *author*, and *price* of the *MyBook* object's instance (with each value on its own line) like so:

```
Title: $title
Author: $author
Price: $price
```

**Note:** The **\$** is prepended to variable names to indicate they are placeholders for variables.

## Sample Input

The following input from stdin is handled by the locked stub code in your editor:

```
The Alchemist  
Paulo Coelho  
248
```

## Sample Output

The following output is printed by your *display()* method:

```
Title: The Alchemist  
Author: Paulo Coelho  
Price: 248
```
